

# Re-import Application

Last Modified on 01.19.23

Application Manager creates application deployments when new application versions are released and the application is imported into Configuration Manager. If you modify a deployment process in AM, those changes will take effect when the next application version is released.

You can re-import the application into Configuration Manager to use the modified settings for the latest already released version. Example case is when you change target collections for the deployments.

1. Remove the application and its deployments from Configuration Manager.
2. Launch Application Manager and select the application you want to re-import.
3. Select **Delete** from top bar, and confirm when prompted.

Application will be re-imported with new settings/deployments during the next 30 minutes. You can select **Start download** to re-import instantly.
