Package Types

Last Modified on 2026-06-24

All these package types come with predefined basic settings, except for **Custom package**, where the settings are blank.

Install MSI – Install an .MSI package by uploading it or providing Application Workspace with the network credentials to access it.

Install Mac App – Install an app via a .PKG file on a macOS platform.

Local application – Configure a launch action for an existing local app from the user's device.

Modify group membership – Change the group memberships for Entra ID and Active Directory.

- For Entra ID, you'll first need to go to **Identity Sources** > **Settings** > **Synchronization** > **Modifications** and select 'Group membership'.
- For LDAP, you'll first need to go to **Identity Sources** > **Settings** > **Synchronization** > **Modifications** and select 'All'.

Remote application – Deploy an app that launches a Remote desktop session.

Remote control – Deploy a remote package to the user device and launch a remote control session for that device via your desired remote desktop software application.

Web application – Make a link available to your users, that launches when they click on the Workspace app or when they log in for example.

Custom package – Unlike the other types of packages that have some settings preconfigure for you to cover the basics, a custom package represents a complete blank template.

The **Superseded by products** information that appears in the **Create new package** window shows all the product versions within Application Workspace Setup Store that supersede the currently selected version.
